Ch 5 1 ModelSelect

Analyze the ISLR (Introduction to Statistical Learning with R) data package's baseball 'Hitters' data frame:

```
library(ISLR)
summary(Hitters)
```

```
##      AtBat            Hits         HmRun            Runs

##                  NA's   :59
```

There are missing values, before we proceed we will remove them:

```
with(Hitters, sum(is.na(Salary)))
```

```
## [1] 59
```

```
Hitters=na.omit(Hitters)
with(Hitters, sum(is.na(Salary)))
```

```
## [1] 0
```

Best Subset regression

We will now use the package `leaps` to evaluate all the best-subset models.

```
library(leaps)
regfit.full = regsubsets(Salary~., data=Hitters)
summary(regfit.full)
```

```
## Subset selection object

## 2  ( 1 ) "*"  " "    " "     " "       " "     " "     " "    " "
## 3  ( 1 ) "*"  " "    " "     " "       "*"     " "     " "    " "
## 4  ( 1 ) "*"  " "    " "     "*"       "*"     " "     " "    " "
## 5  ( 1 ) "*"  " "    " "     "*"       "*"     " "     " "    " "
## 6  ( 1 ) "*"  " "    " "     "*"       "*"     " "     " "    " "
## 7  ( 1 ) " "  " "    " "     "*"       "*"     " "     " "    " "
## 8  ( 1 ) " "  "*"    " "     "*"       "*"     " "     " "    " "
```

By default, it gives the first 8 variables best-subset models. Let's do it again for all the variables:

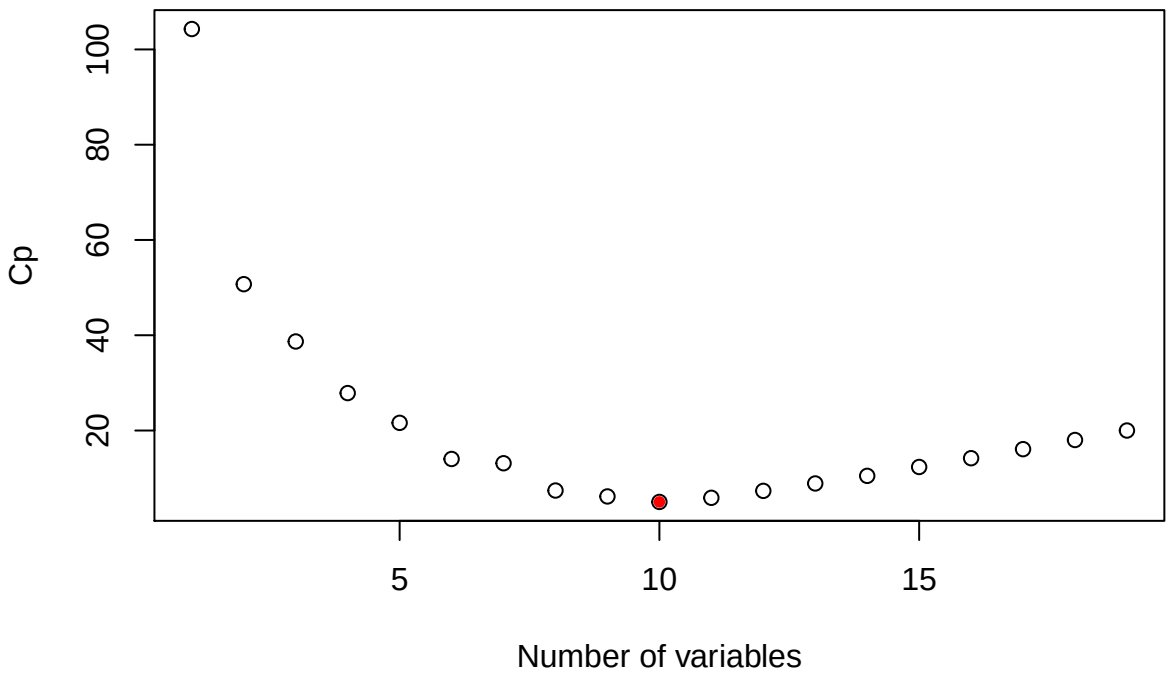
```
regfit.full = regsubsets(Salary~., data=Hitters, nvmax=19)
reg.summary = summary(regfit.full)
names(reg.summary)
```

```
## [1] "which"  "rsq"    "rss"    "adjr2"  "cp"     "bic"    "outmat" "obj"
```

```
plot(reg.summary$cp, xlab="Number of variables", ylab="Cp")
which.min(reg.summary$cp)
```

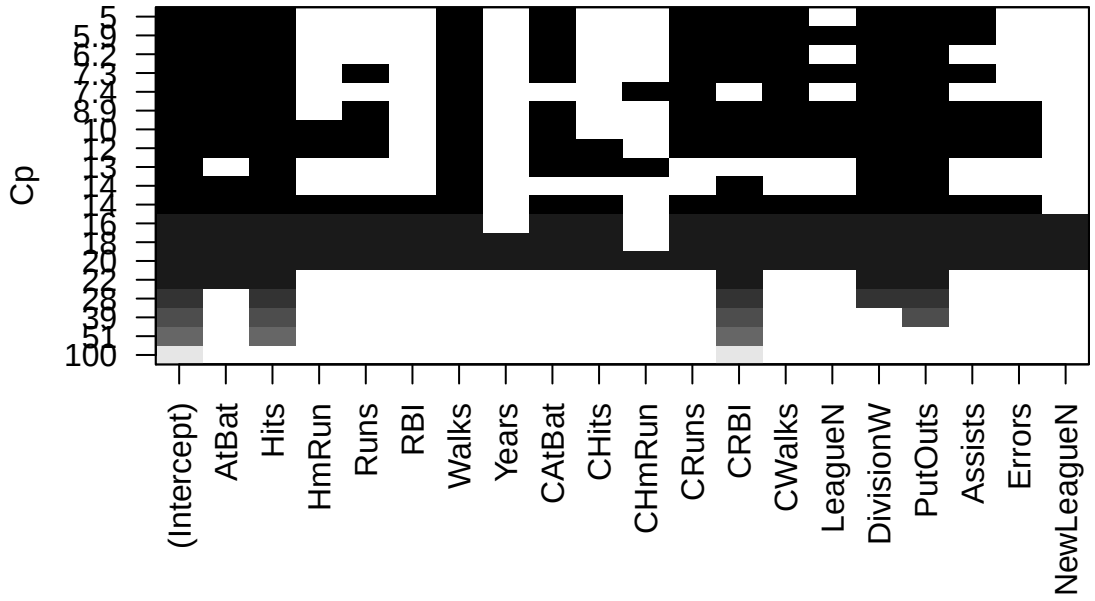
```
## [1] 10
```

```
points(10, reg.summary$cp[10], pch=20, col="red")
```



There is a method for the `regsubset` object:

```
plot(regfit.full,scale="Cp")
```



```
coef(regfit.full, 10)
```

```
##  (Intercept)        AtBat         Hits        Walks       CAtBat
##  162.5354420   -2.1686501    6.9180175    5.7732246   -0.1300798
##        CRuns         CRBI       CWalks    DivisionW      PutOuts
##    1.4082490    0.7743122   -0.8308264 -112.3800575    0.2973726
##      Assists
##    0.2831680
```

Forward Stepwise Selection

We use `regsubset` again, but specify the `method="forward"` option.

```
regfit.fwd = regsubsets(Salary~., data=Hitters, nvmax=19, method="forward")
summary(regfit.fwd)
```

```
## Subset selection object
## Call: regsubsets.formula(Salary ~ ., data = Hitters, nvmax = 19, method = "forward")
## 19 Variables  (and intercept)
##             Forced in Forced out
## AtBat           FALSE      FALSE

```

```
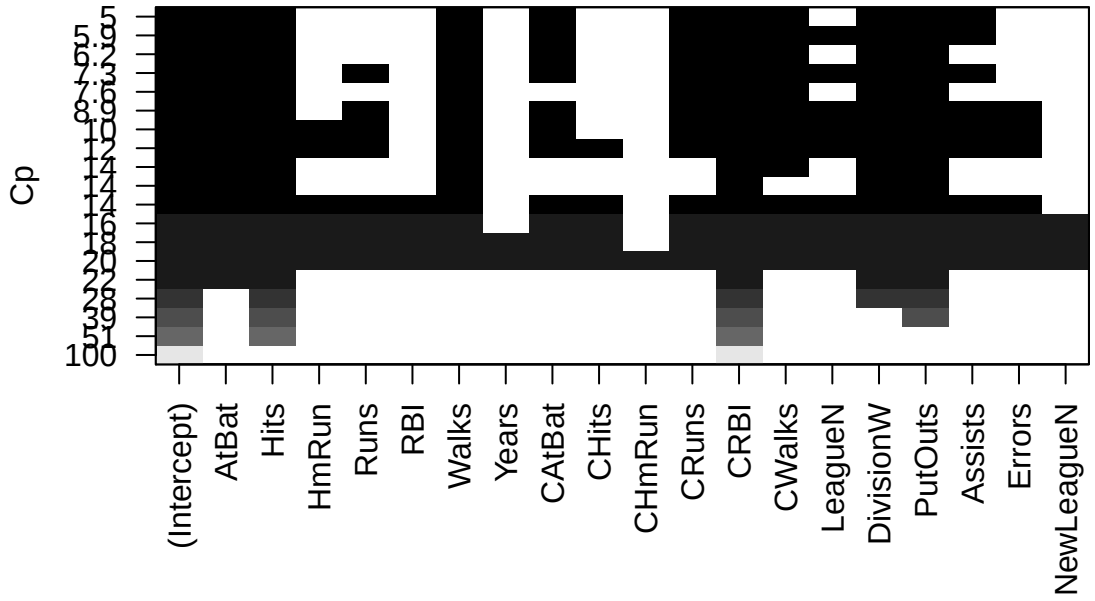
plot(regfit.fwd, scale="Cp")
```



Model Selection Using a Validation Set

Let's make a training and validation set, so that we can choose a good subset model.

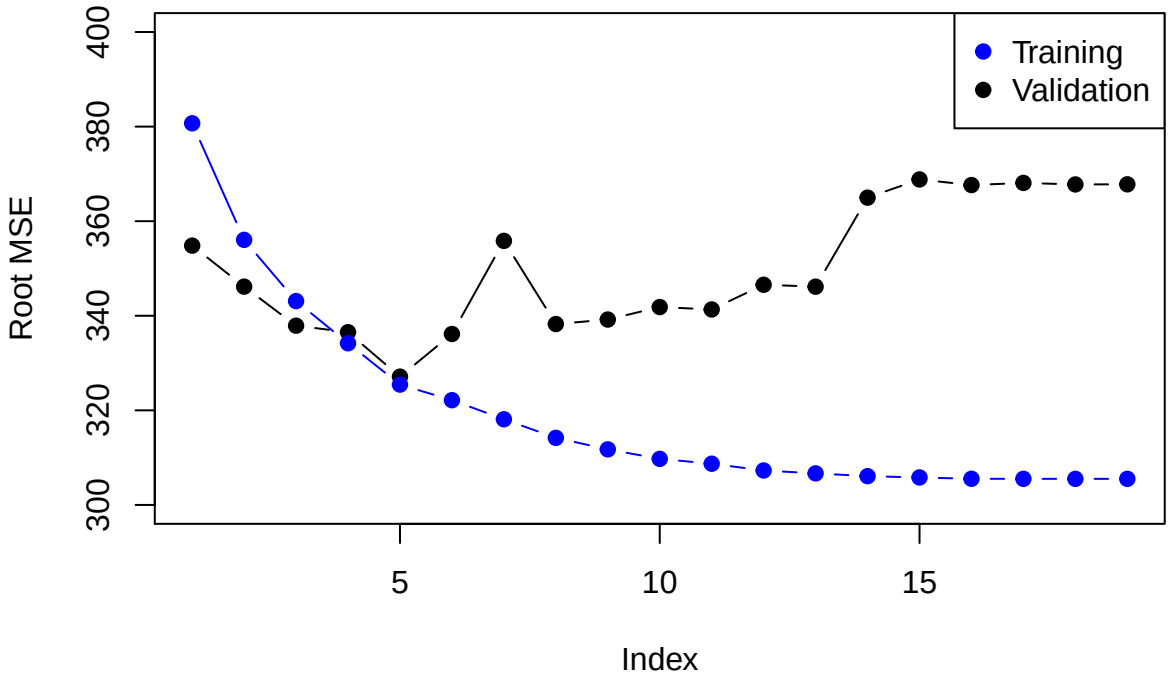
```
dim(Hitters)
```

```
## [1] 263  20
```

```
set.seed(1)
train = sample(seq(263),180,replace=FALSE)
regfit.fwd = regsubsets(Salary~., data=Hitters[train,], nvmax=19, method="forward")
```

Now, we separate the data to two parts, one for training and another for test/validation to make prediction. There is no `prediction` method for `regsubsets`, so we need to write that part. We also create a vector to store the results of the 19 different models.

```
val.errors = rep(NA, 19)
x.test = model.matrix(Salary~., data=Hitters[-train,])
for(i in 1:19){
  coefi = coef(regfit.fwd, id=i)
  pred = x.test[,names(coefi)]%*%coefi
  val.errors[i] = mean((Hitters$Salary[-train]-pred)^2)
}
plot(sqrt(val.errors), ylab="Root MSE", ylim=c(300,400), pch=19, type="b")
points(sqrt(regfit.fwd$rss[-1]/180),col="blue",pch=19,type="b") # -1 excludes null model
legend("topright", legend=c("Training","Validation"),col=c("blue","black"),pch=19)
```



As expected, the model error goes down monotonically as the model gets bigges, but not so for the validation error.

This was a little tedious - not having a `predict` method `regsubsets`. So we will write one!

```
predict.regsubsets = function(object, newdata, id, ...){
  form = as.formula(object$call[[2]])
  mat = model.matrix(form, newdata)
  coefi = coef(object, id=id)
  mat[, names(coefi)] %*% coefi
}
as.formula(regfit.fwd$call[[2]])
```

```
## Salary ~ .
```

Model Seletion by Cross-Validation

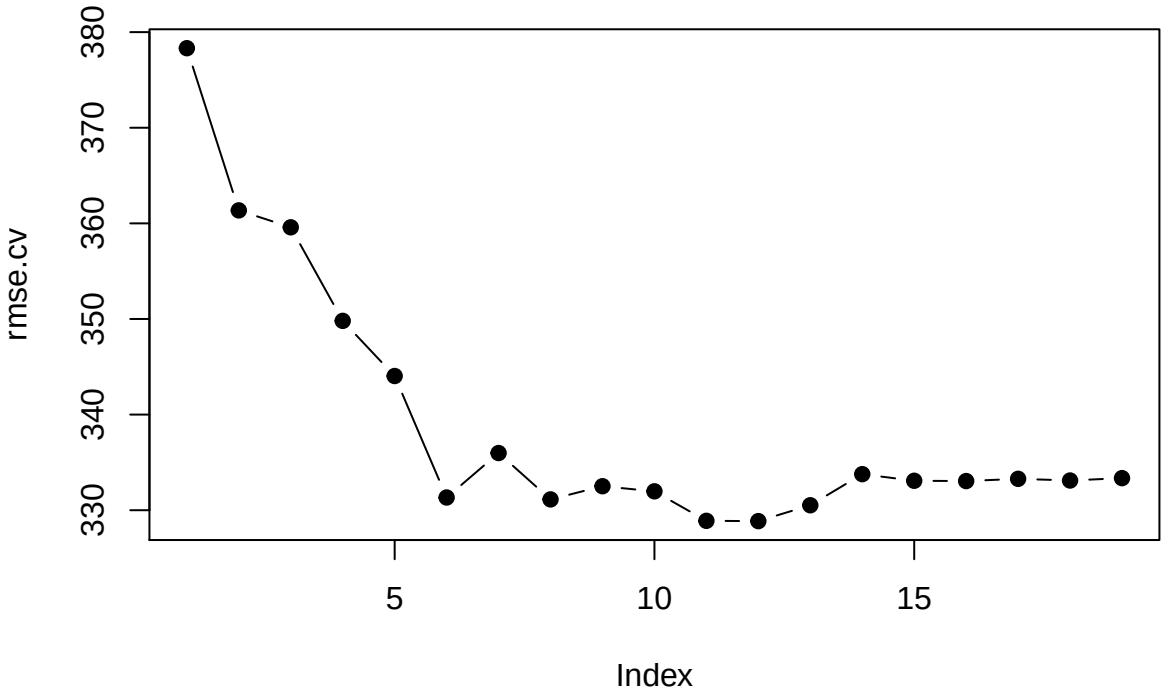
We will do a 10-fold cross-validation.

```
set.seed(11)
folds = sample(rep(1:10,length=nrow(Hitters)))
table(folds)
```

```
## folds
##  1  2  3  4  5  6  7  8  9 10
## 27 27 27 26 26 26 26 26 26 26
```

```
cv.errors = matrix(NA,10,19)
for(k in 1:10){ # Loop for folds
  best.fit = regsubsets(Salary~., data=Hitters[folds!=k,],nvmax=19,method="forward")
  for(i in 1:19){ # Loop for sizes of picked feature best subsets
```

```
    pred = predict(best.fit,Hitters[folds==k,], id=i)
    cv.errors[k,i] = mean((Hitters$Salary[folds==k]-pred)^2)
  }
}
rmse.cv = sqrt(apply(cv.errors,2,mean))
plot(rmse.cv, pch=19, type="b")
```



Ridge regression and the Lasso

We will use the `glmnet` package, which does not use the formula language, so we will set up an `x` and `y`.

```
library(glmnet)
```

```
## Loading required package: Matrix
```

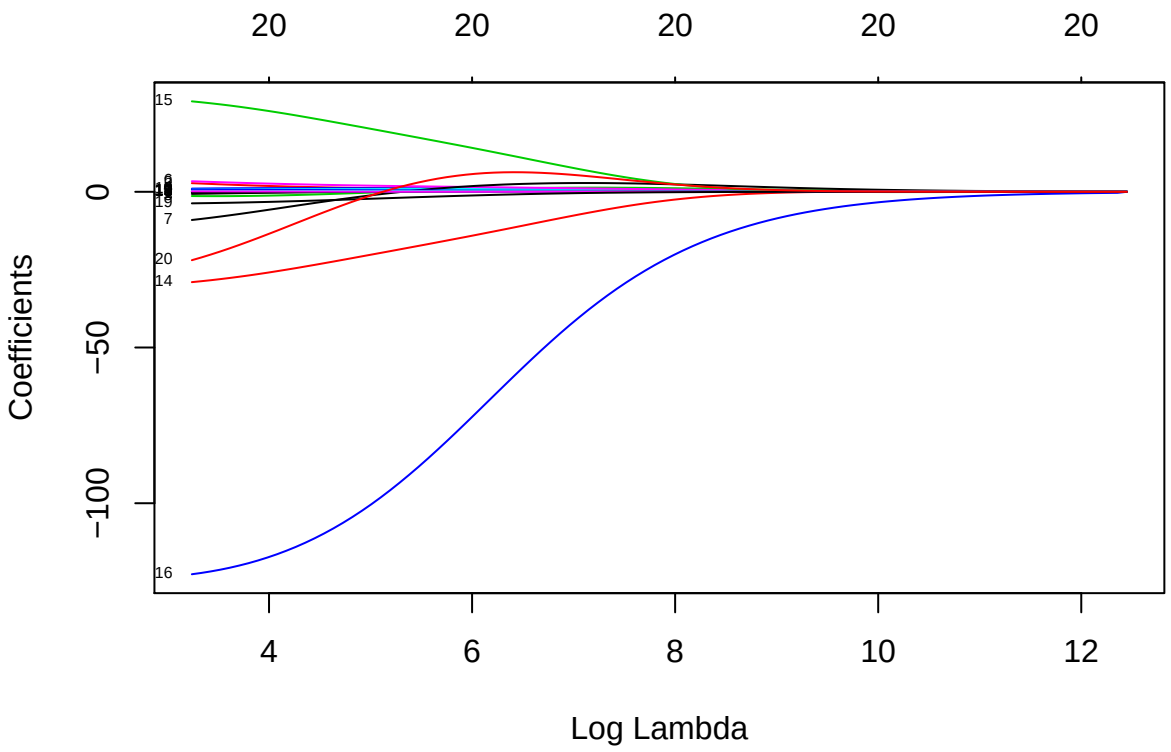
```
## Loading required package: foreach
```

```
## Loaded glmnet 2.0-2
```

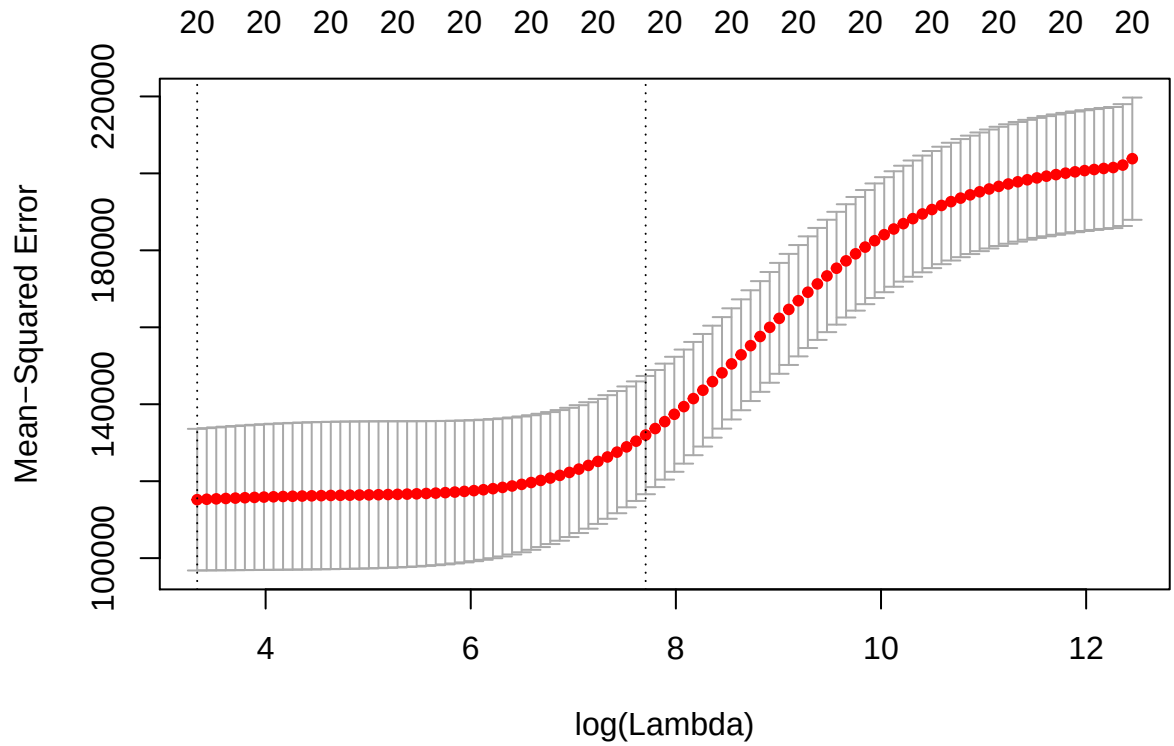
```
x=model.matrix(Salary~.-1, data=Hitters) # -1 means no intercept
y=Hitters$Salary
```

First, we will fit a ridge regression model. This is achived by calling `glmnet` with `alpha=0` (see the help file). There is also a `cv.glmnet` function, which will do the cross validation for us.

```
fit.ridge = glmnet(x,y,alpha=0)
plot(fit.ridge, xvar="lambda", label=TRUE)
```

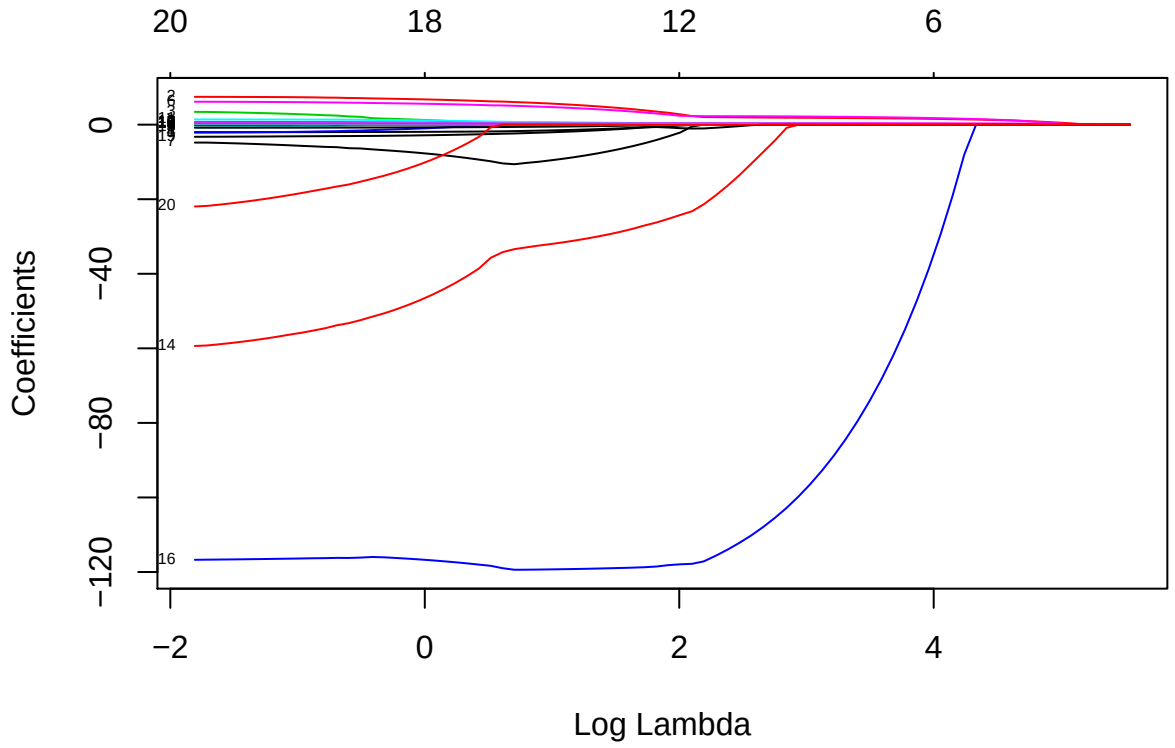


```
cv.ridge = cv.glmnet(x,y,alpha=0)
plot(cv.ridge)
```

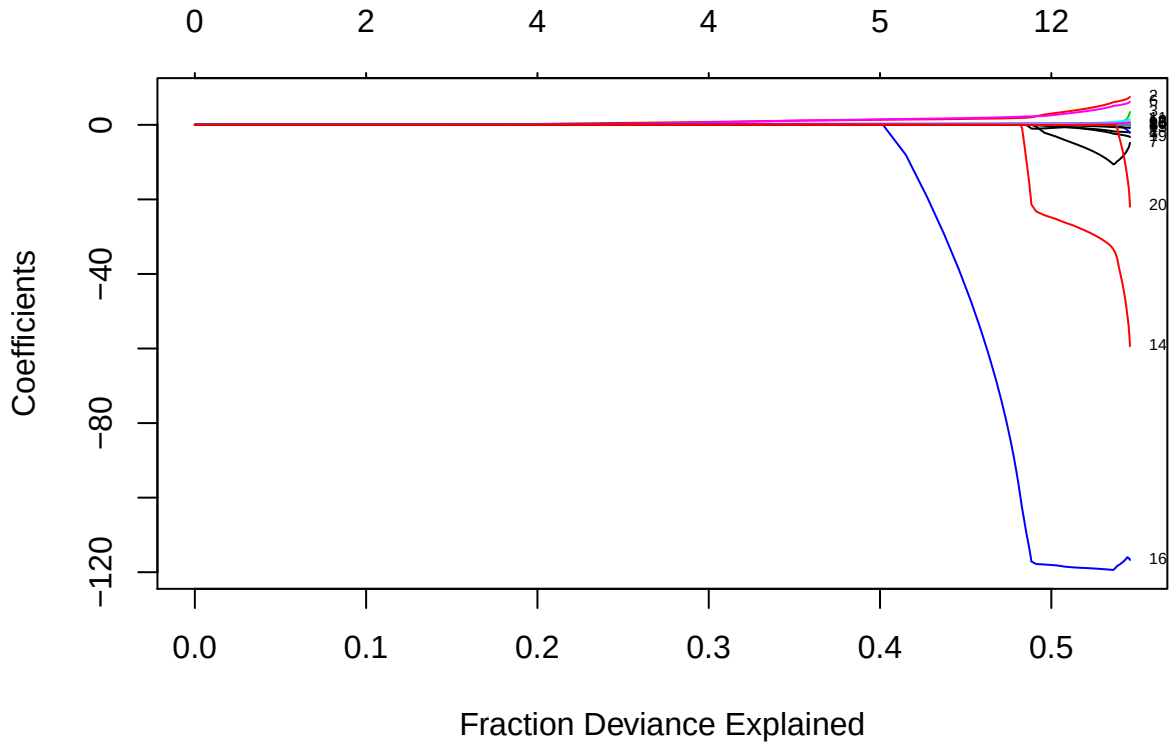


Now, we fit the lasso; in `glmnet` it means `alpha=1`

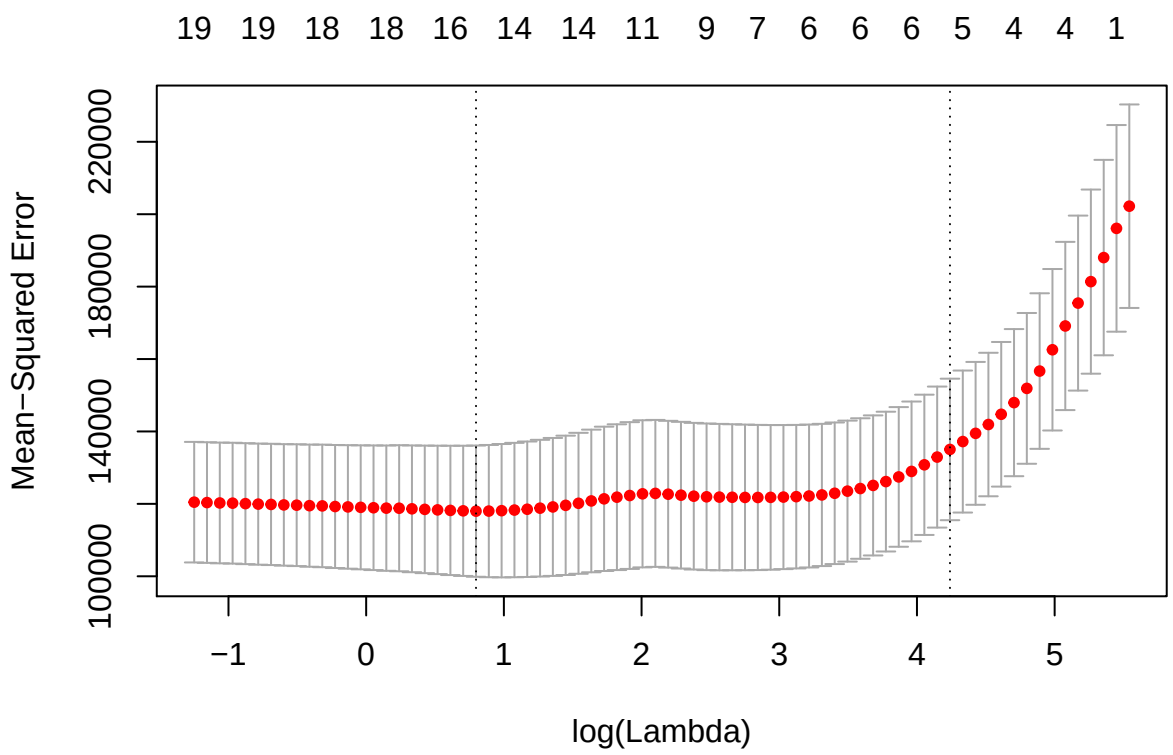
```
fit.lasso = glmnet(x,y)
plot(fit.lasso, xvar="lambda", label=TRUE)
```



```
plot(fit.lasso, xvar="dev", label=TRUE)
```



```
cv.lasso = cv.glmnet(x,y)
plot(cv.lasso)
```



```
coef(cv.lasso) # Picks model one std from minimum to make more parsimonius
```

```
